## ABSTRACT

In this paper, we present a non-oscillatory spectral Fourier method for the solution of hyperbolic partial differential equations. The method is based on adding a nonsmooth function to the trigonometric polynomials which are the usual basis functions for the Fourier method. The high accuracy away from the shock is enhanced by using filters. Numerical results confirm that no oscillations develop in the solution. Also, the accuracy of the spectral solution of the inviscid Burgers equation is shown to be higher than a fixed order.

This research was supported by the National Aeronautics and Space Administration under NASA Contract No. NAS1-18107 while the second author was in residence at the Institute for Computer Applications in Science and Engineering (ICASE), NASA Langley Research Center, Hampton, VA 23665. Additional support was provided by the Air Force Office of Scientific Research under Grant No. 85-0303.

## 1. INTRODUCTION

In this paper, we discuss shock capturing techniques using spectral methods. In particular, we would like to present a nonoscillatory version of the spectral Fourier method when applied to a nonlinear hyperbolic equation. The main difficulty in applying spectral methods to discontinuous problems is of course the Gibbs phenomenon. In fact, this problem exists even in the approximation level. It is well-known that if a discontinuous function  $f(x)$  is approximated by its finite Fourier series  $P_N f$

$$P_N f = \sum_{k=-N}^N \hat{f}_k e^{ikx}, \quad (1.1a)$$

$$\hat{f}_k = \frac{1}{2\pi} \int_0^{2\pi} f(x) e^{-ikx} dx, \quad (1.1b)$$

then the order of convergence of  $P_N f$  to  $f$  is only  $O(\frac{1}{N})$  for each fixed point. Moreover,  $P_N f$  has oscillations of order 1 in a neighborhood of  $O(\frac{1}{N})$  of the discontinuity.

In the applications, we usually have piecewise  $C^\infty$  functions, and in this paper we will consider only those functions. It is known that it is possible to improve the accuracy of the approximation away from the shocks. There are currently two methods (see [7]) that are being used. The first amounts to modifying the Fourier coefficients by multiplying them by a decreasing function  $\sigma(k)$ . Some of the commonly used filters are

$$\begin{aligned} \sigma_k &= e^{-\alpha(\frac{k-k_0}{N})^{2m}} & |k| \geq k_0 \\ \sigma_k &= 1 & |k| < k_0. \end{aligned} \quad (1.2)$$

The second method [1] is based on convoluting the approximation with an appropriate  $C^\infty$  function  $\psi(x, y)$  such that

$$P_N f * \psi(x, y) \sim f(y). \quad (1.3)$$

While both (1.2) and (1.3) are effective away from the discontinuity, they do not eliminate the Gibbs phenomenon in the neighborhood of the shock. This is very important for the stability of the spectral method when applied to partial differential equations. In fact in Section 2 we show that the total variation of  $P_N f$  grows like  $\log N$ . It is easily shown that this is the case also for the filters in (1.2).

In Section 2, we show that by adding a sawtooth function to the basis functions  $e^{ikx}$  one can control the Gibbs phenomenon. This in conjunction with the filters (1.2)-(1.3) yields a high order nonoscillatory approximation to a piecewise  $C^\infty$  function. In Theorem 2, we prove that the total variation of the new approximation converges to that of the approximated function. We also prove that the convergence for the new approximation in  $L^1$  norm is one order higher.

Many modern nonlinear schemes for the solution of the conservation equation

$$u_t + f(u)_x = 0 \quad (1.4)$$

are based on two distinct steps, namely reconstruction and time marching. We use the cell averaging formulation to rewrite (1.4) as

$$\frac{\partial \bar{u}_j}{\partial t} + \frac{1}{\Delta x_j} \left( f(u_{j+\frac{1}{2}}) - f(u_{j-\frac{1}{2}}) \right) = 0 \quad (1.5)$$

where

$$\Delta x_j = x_{j+\frac{1}{2}} - x_{j-\frac{1}{2}}, \bar{u}_j = \frac{1}{\Delta x_j} \int_{x_{j-\frac{1}{2}}}^{x_{j+\frac{1}{2}}} u dx$$

$$f(u_{j+\frac{1}{2}}) = f(u(x_{j+\frac{1}{2}})).$$

The first step, then, is to reconstruct the function  $u(x)$  from  $\bar{u}(x)$ . It is here that we use the nonoscillatory technique developed in Section 2. For the second step, the time marching, we use the third order Runge-Kutta scheme developed in [12]. We try to avoid any modification technique (like the application of limiters) in order to avoid deterioration of the overall accuracy.

We demonstrate in the last section that the procedure applied to several model problems yields indeed nonoscillatory results with an order of accuracy which is higher than algebraic away from the discontinuity.

## 2. NON-OSCILLATORY APPROXIMATION

In this section, we suggest a method to reconstruct a nonoscillatory approximation to a piecewise  $C^\infty$  periodic function from its first  $N$  Fourier coefficients. The approximation is

nonoscillatory in the sense that the total variation of the approximation converges to the total variation of the approximated function. Moreover, the approximation converges in the maximum norm outside a small interval around the point of discontinuity. Applying the filters (1.2)-(1.3) will increase the order of convergence away from the discontinuity, thus providing a nonoscillatory spectral approximation.

For simplicity, assume that  $u(x)$ ,  $0 \leq x \leq 2\pi$  is a periodic piecewise  $C^\infty$  function with only one point of discontinuity at  $x_s$  and denote by  $[u]$  the value of the jump of  $u(x)$  at  $x_s$ , namely

$$[u] = \frac{u(x_s^+) - u(x_s^-)}{2\pi}. \quad (2.1)$$

We assume also that the first  $2N+1$  Fourier coefficients  $\hat{u}_\ell$  of  $u(x)$  are known

$$\hat{u}_\ell = \frac{1}{2\pi} \int_0^{2\pi} u(x) e^{-i\ell x} dx, \quad -N \leq \ell \leq N. \quad (2.2)$$

The objective is to construct a non-oscillatory spectrally accurate approximation to  $u(x)$  from the  $\hat{u}_\ell$ 's. We start by noting that the Fourier coefficients  $\hat{u}_\ell$ 's contain information about the shock position  $x_s$  and the magnitude  $[u]$  of the shock. In fact we can state

**Lemma 1:** *Let  $u(x)$  be a periodic piecewise  $C^\infty$  function with one point of discontinuity  $x_s$ , then for  $|\ell| \geq 1$  and for any  $n > 0$*

$$\hat{u}_\ell = e^{-i\ell x_s} \sum_{k=0}^{n-1} \frac{[u^{(k)}]}{(i\ell)^{k+1}} + \frac{1}{2\pi} \int_0^{2\pi} \frac{[u^{(n)}]}{(i\ell)^n} e^{-i\ell x} dx. \quad (2.3)$$

Proof: Since

$$\hat{u}_\ell = \frac{1}{2\pi} \int_0^{2\pi} u(x) e^{-i\ell x} dx = \frac{1}{2\pi} \int_0^{x_s} u(x) e^{-i\ell x} dx + \frac{1}{2\pi} \int_{x_s}^{2\pi} u(x) e^{-i\ell x} dx$$

we can integrate by parts to get

$$\hat{u}_\ell = e^{-i\ell x_s} \frac{u(x_s^+) - u(x_s^-)}{2\pi i\ell} + \frac{1}{2\pi} \int_0^{2\pi} \frac{u'(x) e^{-i\ell x}}{i\ell} dx \quad (2.4)$$

the rest is obtained by induction. This completes the proof.

As an example, consider the sawtooth function  $F(x, x_s, A)$  defined by

$$F(x, x_s, A) = A \begin{cases} -x & x \leq x_s \\ 2\pi - x & x > x_s \end{cases}. \quad (2.5)$$

Note that the jump of the function  $-[F]$  is  $A$  and all the derivatives are continuous  $\left[\frac{d^k F}{dx^k}\right] = 0$  for  $k \geq 1$ . That means that the expansion (2.3) can be terminated after the first term, yielding the following results for  $\hat{f}_k$  – the Fourier coefficients of  $F(x, x_s, A)$

$$\begin{aligned} \hat{f}_k(x_s, A) &= A \frac{e^{-ikx_s}}{ik} \quad |k| \geq 1 \\ \hat{f}_0(x_s, A) &= A(\pi - x_s). \end{aligned} \quad (2.6)$$

This example suggests that we can rewrite (2.3) as

$$\hat{u}_\ell = \hat{f}_\ell(x_s, [u]) + e^{-i\ell x_s} \sum_{k=1}^{n-1} \frac{[u^{(k)}]}{(i\ell)^{k+1}} + \frac{1}{2\pi} \int_0^{2\pi} \frac{u^{(n)}(x) e^{-i\ell x}}{(i\ell)^n} dx, |\ell| \geq 1. \quad (2.7)$$

The order 1 oscillations in approximating  $u(x)$  by its finite Fourier sum

$$P_N u = \sum_{\ell=-N}^N \hat{u}_\ell e^{i\ell x} \quad (2.8)$$

are caused by the slow convergence of

$$F_N(x, x_s, [u]) = \sum_{\ell=-N}^N \hat{f}_\ell(x_s, [u]) e^{i\ell x} \quad (2.9)$$

to the sawtooth function  $F(x, x_s, [u])$ . Therefore, those oscillations can be eliminated by adding a sawtooth function to the basis of the space to which  $u(x)$  is projected. To be specific, we seek an expansion of the form

$$v_N(x) = \sum_{|\ell| \leq N} a_\ell e^{i\ell x} + \sum_{|\ell| > N} \frac{A}{i\ell} e^{-i\ell y} e^{i\ell x} \quad (2.10)$$

to approximate  $u(x)$ . The  $2N + 3$  unknowns  $a_\ell (|\ell| \leq N)$ ,  $A$  and  $y$  are determined by the orthogonality condition

$$\int_0^{2\pi} (u - v_N) e^{-ikx} dx = 0 \quad |k| \leq N + 2. \quad (2.11)$$

The system of equations (2.11) leads to the following conditions:

$$a_\ell = \hat{u}_\ell \quad |\ell| \leq N \quad (2.12)$$

(where  $\hat{u}_\ell$  are the usual Fourier coefficients of  $u(x)$ , see (2.2)) and

$$\frac{A}{i(N+1)} e^{-i(N+1)y} = \hat{u}_{N+1} \quad (2.13a)$$

$$\frac{A}{i(N+2)} e^{-i(N+2)y} = \hat{u}_{N+2}. \quad (2.13b)$$

Solving (2.13) for  $A$  and  $y$  one gets

$$e^{iy} = \frac{(N+1)\hat{u}_{N+1}}{(N+2)\hat{u}_{N+2}} \quad (2.14a)$$

$$|A| = (N+1)|\hat{u}_{N+1}|. \quad (2.14b)$$

The sign of  $A$  is determined by (2.13).

Note that in the expansion presented in (2.10) the second sum starts at  $|\ell| = N+1$ . This is due to the fact that we make the additional basis function  $F(x, y, A)$  orthogonal to  $e^{ikx}$ , thus we use  $F(x, y, A) - F_N(x, y, A)$  in the expansion (2.10). The procedure described in (2.14) is second order accurate in the location and jump of the shock. In fact, we can state

**Theorem 1:** *Let  $u(x)$  be a piecewise  $C^\infty$  function with one discontinuity at  $x_s$ . Let  $y$  and  $A$  be defined in (2.14) then*

$$\begin{aligned} |y - x_s| &= O\left(\frac{1}{N^2}\right) \\ |A - [u]| &= O\left(\frac{1}{N^2}\right). \end{aligned} \quad (2.15)$$

Proof: From (2.3) we get

$$\begin{aligned} e^{iy} = \frac{(N+1)\hat{u}_{N+1}}{(N+2)\hat{u}_{N+2}} &= \frac{e^{-i(N+1)x_s} \left[ [u] + \frac{[u']}{i(N+1)} + O\left(\frac{1}{(N+1)^2}\right) \right]}{e^{-i(N+2)x_s} \left[ [u] + \frac{[u']}{i(N+2)} + O\left(\frac{1}{(N+1)^2}\right) \right]} \\ &= e^{ix_s} [1 + O(\frac{1}{N^2})]. \end{aligned}$$

By the same token

$$|A| = (N+1)|\hat{u}_{N+1}| = \left[ \left\{ [u] - \frac{[u'']}{(N+1)^2} \right\}^2 + \frac{[u']^2}{(N+1)^2} \right]^{\frac{1}{2}} = |[u]| [1 + O(\frac{1}{N^2})].$$

It should be noted that a better approximation to the shock location  $x_s$  and its magnitude  $[u]$  can be obtained if we add to the basis functions a function of the form

$$\sum_{|l|>N} \left[ \frac{A}{il} + \frac{B}{(il)^2} \right] e^{-ilt_y} \quad (2.16)$$

and extend (2.11) to  $|k| \leq N + 3$ . In practice, however, (2.10) is enough to get a nonoscillatory scheme.

In order to demonstrate that the procedure described in (2.10), (2.12), and (2.14) is indeed nonoscillatory we recall the definition of the total variation of a function.

Definition: The total variation of  $u$  over  $[0, 2\pi]$  –  $TV[u]$  – is defined as

$$TV[u] = \sup \sum_{i=1}^n |u(x_i) - u(x_{i-1})| \quad (2.17)$$

where  $0 \leq x_0 < x_1 < \dots < x_n \leq 2\pi$  is a partition of  $[0, 2\pi]$ . The supremum is taken over all partitions.

It is clear that if  $u'(x) \in L^1$  then

$$TV[u] = \int_0^{2\pi} |u'(\xi)| d\xi. \quad (2.18)$$

If we approximate the function  $u(x)$  by its finite Fourier series  $P_N u$  defined in (2.8), then it is well-known that the total variation of  $P_N u$  need not approximate that of  $u$ . In fact, we can state

**Lemma 2:** *Let the sawtooth function  $F(x, 0, 1)$  and its  $N$  Fourier series  $F_N(x, 0, 1)$  be defined by (2.5) and (2.9), then*

$$TV[F] = 4\pi \quad (2.19)$$

$$TV[F_N] = O(\log N). \quad (2.20)$$

Proof: Equation (2.19) follows directly from the definition of total variation. As for

(2.20) we note that

$$\begin{aligned}
TV[F_N(x, 0, 1)] &= \int_0^{2\pi} |F'_N(x, 0, 1)| dx = \int_0^{2\pi} \left| \sum_{\substack{l=-N \\ l \neq 0}}^N e^{ilx} \right| dx \\
&= \int_0^{2\pi} \left| \frac{\sin(N + \frac{1}{2})x}{\sin \frac{1}{2}x} - 1 \right| dx \\
&= \int_0^{2\pi} \left| \frac{\sin(N + \frac{1}{2})x}{\sin \frac{1}{2}x} \right| dx + O(1).
\end{aligned} \tag{2.21}$$

The first term on the right hand side of (2.21) is the Lebesgue constant. It is known ([13], p. 67) that it grows like  $(\log N)$ . Hence (2.20). We can therefore conclude that  $TV(P_N u)$  does not converge to  $TV[u]$ . This reflects the existence of large oscillations in the neighborhood of the discontinuities.

The situation is different for  $v_N$  defined in (2.10). In fact, we can state

**Theorem 2:** *Let  $u(x)$  be a piecewise  $C^\infty$  periodic function with one point of discontinuity  $x_s$ , and a jump of  $[u]$ . Let  $A$  and  $y$  be such that*

$$\begin{aligned}
|y - x_s| &= \Delta_1 \\
|A - [u]| &= \Delta_2.
\end{aligned} \tag{2.22}$$

Let  $v_N$  be defined in (2.10), then

$$TV[v_N] \leq TV[u] + L_0 \frac{\log N}{N} + L_1 \Delta_1 N \log N + L_2 \Delta_2 \log N \tag{2.23}$$

$$\|v_N - u\|_{L^1} \leq C_0 \frac{\log N}{N^2} + C_1 \Delta_1 \log N + C_2 \Delta_2. \tag{2.24}$$

We present the proof in a series of Lemmas in order to clarify the role of each one of the terms on the right hand sides of (2.23) and (2.24).

**Lemma 3:** *Let  $F_N(x, \alpha, 1)$  and  $F_N(x, \beta, 1)$  be defined by (2.6)-(2.9) and  $\Delta = \alpha - \beta > 0$ . Then if  $\Delta \leq \frac{1}{N}$ :*

$$TV[F_N(x, \alpha, 1) - F_N(x, \beta, 1)] = O(\Delta N \log N) \tag{2.25}$$

$$\|F_N(x, \alpha, 1) - F_N(x, \beta, 1)\|_{L^1} = O(\Delta \log N). \tag{2.26}$$

Proof: Since  $F_N(x, \alpha, 1)$ ,  $F_N(x, \beta, 1)$  are trigonometrical polynomials they are  $C^\infty$  functions. Therefore,

$$\begin{aligned}
TV[F_N(x, \alpha, 1) - F_N(x, \beta, 1)] &= \int_0^{2\pi} |F'_N(x, \alpha, 1) - F'_N(x, \beta, 1)| dx \\
&= \int_0^{2\pi} \left| \sum_{|\ell| \leq N} [e^{i\ell(x-\alpha)} - e^{i\ell(x-\beta)}] \right| dx \\
&= 4 \int_0^{2\pi} \left| \sum_{\ell=1}^N \sin \ell \left(x - \frac{\alpha + \beta}{2}\right) \sin \ell \frac{\alpha - \beta}{2} \right| dx.
\end{aligned} \tag{2.27}$$

Upon defining  $\sigma_\ell = \sin \ell \frac{\alpha - \beta}{2}$ , we can rewrite (2.27) as

$$TV[F_N(x, \alpha, 1) - F_N(x, \beta, 1)] = 4 \int_0^{2\pi} \left| \sum_{\ell=1}^N \sigma_\ell \sin \ell \xi \right| d\xi \tag{2.28}$$

we note that  $\sigma_\ell$  are positive and monotone in  $\ell$ ,  $\sigma_{\ell-1} - \sigma_\ell < 0$ . Define now

$$B_\ell(\xi) = \sum_{k=0}^{\ell} \sin k \xi \tag{2.29}$$

to get

$$\begin{aligned}
\sum_{\ell=1}^N \sigma_\ell \sin \ell \xi &= \sum_{\ell=1}^N \sigma_\ell (B_\ell(\xi) - B_{\ell-1}(\xi)) \\
&= \sum_{\ell=1}^N (\sigma_{\ell-1} - \sigma_\ell) B_{\ell-1} + \sigma_N B_N.
\end{aligned} \tag{2.30}$$

Therefore,

$$\int_0^{2\pi} \left| \sum_{\ell=1}^N \sigma_\ell \sin \ell \xi \right| d\xi \leq \sigma_N \int_0^{2\pi} |B_N(\xi)| d\xi + \sum_{\ell=1}^N (\sigma_\ell - \sigma_{\ell-1}) \int_0^{2\pi} |B_{\ell-1}(\xi)| d\xi. \tag{2.31}$$

Denote now by  $\mu$

$$\mu = \max_{1 \leq \ell \leq N} \int_0^{2\pi} |B_\ell(\xi)| d\xi \tag{2.32}$$

from (2.28) and (2.31)

$$TV[F_N(x, \alpha, 1) - F_N(x, \beta, 1)] \leq 8\mu\sigma_N. \tag{2.33}$$

In order to estimate  $\mu$ , we first note that

$$B_\ell(\xi) = \sin \frac{(\ell+1)\xi}{2} \cdot \frac{\sin \frac{\ell\xi}{2}}{\sin \frac{\xi}{2}}. \tag{2.34}$$

Therefore,

$$\int_0^{2\pi} |B_\ell(\xi)| d\xi \leq \int_0^{2\pi} \frac{|\sin \frac{\ell\xi}{2}|}{\sin \frac{\xi}{2}} d\xi = \mu_\ell. \quad (2.35)$$

But  $\mu_\ell$  is exactly the Lebesgue constant, therefore,

$$\mu_\ell = O(\ell n \ell). \quad (2.36)$$

Since  $\sigma_N \leq N\Delta$ , we get

$$TV[F_N(x, \alpha, 1) - F_N(x, \beta, 1)] = O(\Delta N \log N).$$

To obtain (2.26), we follow the same arguments as above. Similar to (2.27) and (2.28) we have

$$\int_0^{2\pi} |F_N(x, \alpha, 1) - F_N(x, \beta, 1)| dx \leq 2\pi\Delta + 4 \int_0^{2\pi} \left| \sum_{\ell=1}^N \hat{\sigma}_\ell \cos \ell\xi \right| d\xi \quad (2.37)$$

where  $\hat{\sigma}_\ell = \frac{\sigma_\ell}{\ell}$ ,  $1 \leq \ell \leq N$ .  $\hat{\sigma}_\ell$ 's are positive and monotone in  $\ell$ ,  $\sigma_\ell - \sigma_{\ell-1} < 0$ . If we define

$$\begin{aligned} \hat{B}_\ell(\xi) &= \sum_{k=1}^{\ell} \cos k\xi = \cos \frac{(\ell+1)\xi}{2} \cdot \frac{\sin \frac{\ell\xi}{2}}{\sin \frac{\xi}{2}}. \\ \hat{B}_0(\xi) &= 0 \end{aligned} \quad (2.38)$$

Then similar to (2.33) we have

$$\int_0^{2\pi} |F_N(x, \alpha, 1) - F_N(x, \beta, 1)| dx \leq 2\pi\Delta + 8\mu\hat{\sigma}_1 \quad (2.39)$$

where  $\mu$  is defined in (2.32) with  $B_\ell$  replaced by  $\hat{B}_\ell$  of (2.38). Notice that (2.35) also holds for  $\hat{B}_\ell(x)$  and  $|\hat{\sigma}_1| \leq \Delta$ . (2.26) now follows from (2.35), (2.37), and (2.39).

**Lemma 4:** Let  $F_N(x, \alpha, A)$  and  $F_N(x, \beta, B)$  be defined in (2.6)-(2.9). Denote

$$|\alpha - \beta| = \Delta_1, \quad |A - B| = \Delta_2. \quad (2.40)$$

Then

$$TV[F_N(x, \alpha, A) - F_N(x, \beta, B)] \leq K_1 \Delta_1 N \log N + K_2 \Delta_2 \log N \quad (2.41)$$

$$\|F_N(x, \alpha, A) - F_N(x, \beta, B)\|_{L^1} \leq C_1 \Delta_1 \log N + C_2 \Delta_2 \quad (2.42)$$

for  $K_1, K_2, C_1, C_2$  independent of  $N$ .

Proof:

$$\begin{aligned} TV[F_N(x, \alpha, A) - F_N(x, \beta, B)] &\leq TV[F_N(x, \alpha, A) - F_N(x, \beta, A)] \\ &+ TV[F_N(x, \beta, A) - F_N(x, \beta, B)]. \end{aligned} \quad (2.43)$$

The first term in the right hand side of (2.37) is bounded by (2.25), the second term

$$\begin{aligned} TV[F_N(x, \beta, A) - F_N(x, \beta, B)] &= TV[(A - B) \sum_{\substack{\ell=-N \\ \ell \neq 0}}^N \frac{e^{i\ell(x-\beta)}}{i\ell}] \\ &\leq |A - B| \int_0^{2\pi} \left| \sum_{\substack{\ell=-N \\ \ell \neq 0}}^N e^{i\ell(x-\beta)} \right| dx \\ &\leq K_2 \Delta_2 \log N. \end{aligned} \quad (2.44)$$

Similarly we have

$$\begin{aligned} \|F_N(x, \alpha, A) - F_N(x, \beta, B)\|_{L^1} &\leq \|F_N(x, \alpha, A) - F_N(x, \beta, A)\|_{L^1} + \|F_N(x, \beta, A) \\ &- F_N(x, \beta, B)\|_{L^1} = \|F_N(x, \alpha, A) - F_N(x, \beta, A)\|_{L^1} + |A - B| \|F_N(x, \beta, 1)\|_{L^1}. \end{aligned} \quad (2.45)$$

The first term on the right side of (2.45) is bounded by (2.26). The second term

$$|A - B| \|F_N(x, \beta, 1)\|_{L^1} = \Delta_2 \|F_N(x, \beta, 1)\|_{L^1} \leq C_2 \Delta_2 \quad (2.46)$$

(2.42) follows from (2.45), (2.46), so the Lemma is proven.

**Lemma 5:** Let  $S(x, \alpha, A)$  and  $S_N(x, \alpha, A)$  be defined by

$$\begin{aligned} S(x, \alpha, A) &= A \sum_{\ell=-\infty}^{\infty} \frac{e^{i\ell(x-\alpha)}}{(i\ell)^2} \\ S_N(x, \alpha, A) &= A \sum_{\ell=-N}^N \frac{e^{i\ell(x-\alpha)}}{(i\ell)^2}. \end{aligned} \quad (2.47)$$

Then

$$TV[S(x, \alpha, A) - S_N(x, \alpha, A)] \leq K_3 \frac{\log N}{N} \quad (2.48)$$

$$\|S(x, \alpha, A) - S_N(x, \alpha, A)\|_{L^1} \leq K_4 \frac{\log N}{N^2}, \quad (2.49)$$

for  $K_3, K_4$  independent of  $N$ .

Proof: It is clear that

$$TV(S(x, \alpha, A) - S_N(x, \alpha, A)) = \int_0^{2\pi} |F(x, \alpha, A) - F_N(x, \alpha, A)| dx$$

the estimates (2.48)-(2.49) follow from [13, p. 185].

We are ready now to prove Theorem 2.

Proof of Theorem 2: First we prove (2.23). In view of (2.3), we can write

$$u = F(x, x_s, [u]) + S(x, x_s, [u']) + g(x) \quad (2.50)$$

and therefore

$$P_N u = F_N(x, x_s, [u]) + S_N(x, x_s, [u']) + P_N g(x) \quad (2.51)$$

we can also rewrite (2.10) as

$$v_N(x) = P_N u + F(x, y, A) - F_N(x, y, A) \quad (2.52)$$

hence

$$v_N(x) = F_N(x, x_s, [u]) + S_N(x, x_s, [u']) + P_N g(x) + F(x, y, A) - F_N(x, y, A)$$

or

$$\begin{aligned} v_N(x) &= [F_N(x, x_s, [u]) - F_N(x, y, A)] + [F(x, y, [u]) + S(x, y, [u']) + g(x - y + x_s)] \\ &+ [S_N(x, x_s, [u']) - S(x, y, [u'])] + [P_N g(x) - g(x - y + x_s)] \\ &+ [F(x, y, A) - F(x, y, [u])]. \end{aligned} \quad (2.53)$$

The second term on the right hand side is just the original function  $u$  shifted

$$F(x, y, [u]) + S(x, y, [u']) + g(x - y + x_s) = u(x - y + x_s) \quad (2.54)$$

also from (2.48)

$$\begin{aligned} TV[S_N(x, x_s, [u']) - S(x, y, [u'])] &\leq TV[S_N(x, x_s, [u']) - S_N(x, y, [u'])] \\ &+ TV[S_N(x, y, [u']) - S(x, y, [u'])] \leq K \frac{\log N}{N} \end{aligned} \quad (2.55)$$

and finally since  $g(x)$  is smooth enough

$$TV[P_N g - g(x - y + x_s)] \leq \frac{K}{N}. \quad (2.56)$$

Therefore from (2.53) and Lemma 4 and Lemma 5

$$TV[v_N(x)] \leq TV[u] + L_0 \frac{\log N}{N} + L_1 \Delta_1 N \log N + L_2 \Delta_2 \log N. \quad (2.57)$$

Next we prove (2.24) following the same argument above. From (2.50), (2.51), and (2.52)

$$\begin{aligned} v_N(x) - u(x) &= [F_N(x, x_s, [u]) - F_N(x, y, A)] + [S_N(x, x_s, [u']) - S(x, x_s, [u'])] \\ &+ [F(x, y, A) - F(x, x_s, [u])] + [P_N g(x) - g(x)]. \end{aligned} \quad (2.58)$$

The first term will be bounded by (2.42), the second term by (2.49), the third term

$$\int_0^{2\pi} |F(x, y, A) - F(x, x_s, [u])| dx \leq C_1 \Delta_1 + C_2 \Delta_2. \quad (2.59)$$

Now since  $g(x)$  is smooth enough, we have

$$\|P_N g - g\|_{L^1} = O\left(\frac{1}{N^2}\right). \quad (2.60)$$

Therefore from Lemma 4, Lemma 5 and (2.59)-(2.60)

$$\|v_N - u\|_{L^1} \leq C_0 \frac{\log N}{N^2} + C_1 \Delta_1 \log N + C_2 \Delta_2,$$

and the proof is completed.

**Corollary:** The method suggested in (2.15) yields

$$|A - [u]| = O\left(\frac{1}{N^2}\right) \text{ and } |y - x_s| = O\left(\frac{1}{N^2}\right)$$

and therefore

$$TV[v_N] \leq TV[u] + K \frac{\log N}{N} \quad (2.61)$$

$$\|v_N - u\|_{L^1} \leq C \frac{\log N}{N^2}. \quad (2.62)$$

Thus, the total variation of  $v_N$  converges to that of  $u$ .  $v_N$  converges to  $u$  in  $L^1$  norm one order higher than  $P_N u$  for which the rate of its convergence in  $L^1$  is  $O(\frac{\log N}{N})$ . The method, therefore, yields a reconstruction technique which is total variation bounded.

We conclude this section by pointing out that a similar result for collocation method and/or for Chebyshev expansions can be developed, along the same lines. Computationally, we observe similar results for Galerkin and collocation methods (see Section 4). In practice, collocation is used more often than Galerkin, especially when solving a nonlinear PDE (Section 3).

### 3. NON-OSCILLATORY SPECTRAL SCHEMES

In this section, we apply the techniques discussed in Section 2 to solve the PDE (1.4):

$$u_t + f(u)_x = 0 \quad (3.1a)$$

$$u(x, 0) = u^0(x). \quad (3.1b)$$

If the cell average of  $u$  is defined by

$$\bar{u}(x, t) = \frac{1}{\Delta x} \int_{x-\frac{\Delta x}{2}}^{x+\frac{\Delta x}{2}} u(\xi, t) d\xi, \quad (3.2)$$

then (3.1) can be rewritten as

$$\frac{\partial}{\partial t} \bar{u}(x, t) + \frac{1}{\Delta x} \left[ f\left(u\left(x + \frac{\Delta x}{2}, t\right)\right) - f\left(u\left(x - \frac{\Delta x}{2}, t\right)\right) \right] = 0 \quad (3.3a)$$

$$\bar{u}(x, 0) = \bar{u}^0(x). \quad (3.3b)$$

Hence a semi-discrete conservative scheme

$$\frac{d}{dt} \bar{u}_j = L(\bar{u})_j = -\frac{1}{\Delta x} (\hat{f}_{j+\frac{1}{2}} - \hat{f}_{j-\frac{1}{2}}) \quad (3.4)$$

will be of high order if the numerical flux  $\hat{f}_{j+\frac{1}{2}}$  approximates  $f(u(x_j + \frac{\Delta x}{2}, t))$  to high order. This is the approach used in the MUSCL type semi-discrete finite difference TVD and ENO schemes [10],[4]. Notice that (3.4) is a scheme for the cell averages  $\bar{u}_j$ . However, in evaluating  $\hat{f}_{j+\frac{1}{2}}$ , which should approximate  $f(u(x_j + \frac{\Delta x}{2}, t))$ , we also need accurate point values  $u_{j+\frac{1}{2}} = u(x_j + \frac{\Delta x}{2}, t)$ . For finite difference schemes, the reconstruction from cell averages to point values is a major issue and causes difficulties, especially in several space dimensions [4],[5]. For spectral methods, this is very simple because  $\bar{u}$  is just the convolution of  $u$  with the characteristic function of  $(x_{j-\frac{1}{2}}, x_{j+\frac{1}{2}})$ . To be precise, if

$$u(x) = \sum_{\ell=-N}^N a_\ell e^{i\ell x} \quad (3.5)$$

(we have suppressed the time variable  $t$ ), then

$$\bar{u}(x) = \sum_{\ell=-N}^N \bar{a}_\ell e^{i\ell x} \quad (3.6)$$

with

$$\bar{a}_\ell = \sigma_\ell a_\ell, \quad \sigma_\ell = \frac{\sin(\frac{\ell\Delta x}{2})}{\frac{\ell\Delta x}{2}} \text{ for } 0 < |\ell| \leq N, \quad \sigma_0 = 1. \quad (3.7)$$

Notice that for collocation or Galerkin with  $\Delta x = \frac{2\pi}{2N}$ , we have  $|\frac{\ell\Delta x}{2}| \leq \frac{\pi}{2}$  for  $|\ell| \leq N$ , hence  $\frac{2}{\pi} \leq \sigma_\ell \leq 1$ . The division or multiplication by  $\sigma_\ell$  thus causes no stability difficulty. We point out that  $\sigma_\ell$  resembles the Lanczos filter [8], which in our notations is  $\frac{\sin(\frac{\ell\Delta x}{2})}{\frac{\ell\Delta x}{2}}$ , and approaches zero when  $|\ell| \rightarrow N$ .

The easy transform between  $u$  and  $\bar{u}$  is also valid in several space dimensions and for other spectral expansions (e.g., Chebyshev expansions). We omit the details.

We now state our scheme as (3.4) with

$$\hat{f}_{j+\frac{1}{2}} = f(v_N(x_{j+\frac{1}{2}}, t)) \quad (3.8)$$

where  $v_N$  is defined by (2.10). We obtain the Fourier coefficients  $\bar{a}_\ell$  of  $\bar{u}$  from  $\{\bar{u}_j\}$  by collocation, and obtain  $a_\ell$  of  $u$  needed in (2.10) by (3.7). The main difference between the conventional spectral method and the current approach is that we use the non-oscillatory reconstruction  $v_N$  instead of the oscillatory  $P_N u$  in (3.8).

The scheme, as it stands, can only treat a solution of not more than one discontinuity. However, it can be easily generalized.

We remark that if  $u$  is smooth, (2.10) keeps spectral accuracy because  $A$  determined by (2.14) will be spectrally small.

To discretize (3.4) in time we use the high order TVD Runge-Kutta methods in [12]:

$$\begin{aligned}\bar{u}^{(i)} &= \sum_{k=0}^{i-1} [\alpha_{ik} \bar{u}^{(k)} + \beta_{ik} \Delta t L(\bar{u}^{(k)})], \quad i = 1, \dots, r \\ \bar{u}^{(0)} &= \bar{u}^n, \quad \bar{u}^{(r)} = \bar{u}^{n+1}.\end{aligned}\tag{3.9}$$

In Section 4, we use a third order scheme  $r = 3$  with  $\alpha_{10} = \beta_{10} = 1$ ,  $\alpha_{20} = \frac{3}{4}$ ,  $\beta_{20} = 0$ ,  $\alpha_{21} = \beta_{21} = \frac{1}{4}$ ,  $\alpha_{30} = \frac{1}{3}$ ,  $\beta_{30} = \alpha_{31} = \beta_{31} = 0$ ,  $\alpha_{32} = \beta_{32} = \frac{2}{3}$ . We use a small  $\Delta t$  so that the temporal error can be neglected. These methods are TVD (or TVB) if the Euler forward version of (3.4) is TVD (or TVB). In light of (2.61), we expect the total variation of (3.4)-(3.8)-(3.9) to grow at most at the rate of  $O(\ell n N)$ . In practice we observe stable results (Section 4).

As in the finite difference case [10] [11], we may also apply limiters to obtain provable TVB schemes while still keeping spectral accuracy. Let

$$\tilde{u}_j = u_{j+\frac{1}{2}} - \bar{u}_j, \quad \tilde{\tilde{u}}_{j+1} = \bar{u}_{j+1} - u_{j+\frac{1}{2}}\tag{3.10}$$

where  $u_{j+\frac{1}{2}} = v_N(x_{j+\frac{1}{2}}, t)$  in (3.8). We limit the increments by

$$\tilde{u}_j^{(mod)} = m(\tilde{u}_j, \Delta_+ \bar{u}_j, \Delta_- \bar{u}_j), \quad \tilde{\tilde{u}}_{j+1}^{(mod)} = m(\tilde{\tilde{u}}_{j+1}, \Delta_+ \bar{u}_j, \Delta_- \bar{u}_j)\tag{3.11}$$

where  $m$  is the minmod function with TVB correction:

$$m(a_1, \dots, a_k) = \begin{cases} a_1, & \text{if } |a_1| \leq M \Delta x^2 \\ s \cdot \min_{1 \leq i \leq k} |a_i|, & \text{if } |a_1| > M \Delta x^2 \text{ and } \text{sign}(a_i) = s \forall i \\ 0, & \text{otherwise} \end{cases}\tag{3.12}$$

with  $M = \frac{2}{3} M_2$  or  $M = M_j = \frac{2}{9} (3 + 10 M_2) M_2 \cdot \frac{\Delta x^2}{\Delta x^2 + |\Delta_+ \bar{u}_j| + |\Delta_- \bar{u}_j|}$ . Here  $M_2$  is the maximum of  $|u_{xx}^0|$  in some region around the smooth critical points of  $u^0(x)$ . See [11], [2].

The flux (3.8) is modified to

$$\hat{f}_{j+\frac{1}{2}} = h(\bar{u}_j + \tilde{u}_j^{(mod)}, \bar{u}_{j+1} - \tilde{u}_{j+1}^{(mod)}) \quad (3.13)$$

where  $h$  is any monotone flux [3]. We then have the following Lemma.

**Lemma 6:** *Scheme (3.9)-(3.13) is TVB and formally spectrally accurate in space (i.e., the spatial local truncation error in smooth region is spectrally small), if the filtering (1.3) is used.*

Proof: The proof for TVB can be found in [10], [11]. By [1], the local truncation error is spectrally small in smooth regions if the limiter (3.11) returns the first argument. The proof that (3.11) always returns the first argument in smooth regions, including at critical points, can be found in [2].

We remark that the scheme (3.4)-(3.8)-(3.9), with or without the TVB limiting (3.11), yields almost identical results in our numerical examples (Section 4). This indicates the good stability property of the scheme (3.4)-(3.8)-(3.9). We also remark that (3.13) yields a TVB scheme regardless of the underlying method (3.4). However, accuracy in smooth regions may be lost if the underlying method (3.4) is globally oscillatory, because the limiters (3.11) may be enacted in smooth regions to counter-balance these spurious oscillations. Numerical examples in Section 4 verify these remarks. In [9], McDonald also used some limiters to obtain a TVD spectral scheme. However, the accuracy in smooth regions is questionable due to the above remarks.

## 4. NUMERICAL RESULTS

We use several numerical examples to illustrate the methods introduced in the previous sections.

Example 1: We use the approximation (2.10)-(2.12)-(2.14) on the following function

$$u(x) = \begin{cases} \sin \frac{x}{2}, & 0 \leq x \leq 0.9 \\ -\sin \frac{x}{2}, & 0.9 < x < 2\pi. \end{cases} \quad (4.1)$$

Notice that  $[u^{(k)}] \neq 0$  for all  $k \geq 0$ . Both Galerkin and collocation methods are tested. Exponential filters (1.2) with  $m = 4$ ,  $k_0 = 0$  is used.

In Table 1, we list the errors of the shock location and shock strength determined by (2.14). Notice that the second order accuracy (2.15) is verified.

Figure 1 displays the numerical solution of Galerkin approximation (2.10)-(2.12)-(2.14) with  $N = 64$ . Figure 2 is the error of the approximation on a logarithm scale. We have found the same kind of results for collocation approximation. In Table 2, we list the  $L^1$  error and numerical order in smooth region (in this case, we define the smooth region to be 0.8 away from discontinuity). We can see Galerkin and collocation have the same order of accuracy. There is no  $O(1)$  error near the discontinuity, overall we achieve  $O(\frac{\log N}{N^2})$  for  $L^1$  convergence, verifying (2.62). For comparison, we refer the reader to [7].

Example 2: We apply (2.10)-(2.12)-(2.14) on a discontinuous function which is the steady state solution of an astrophysics problem [6]. Figure 3 is  $v_N$  in (2.10) with  $N = 32$ . For comparison, Figure 4 is the usual Galerkin approximation  $P_N u$  with  $N = 32$ . The improvement is apparent.

Example 3: We solve the Burgers' equation

$$\begin{aligned} u_t + \left(\frac{u^2}{2}\right)_x &= 0 \\ u(x, 0) &= 0.3 + 0.7 \sin x \end{aligned} \tag{4.2}$$

using scheme (3.4)-(3.8)-(3.9) and (3.4)-(3.9)-(3.13). We find the shock location and strength with (2.14). In practice, we do not use the last part of the Fourier modes of the numerical solutions in (2.14). In our computation, we find that the coefficients of modes in the range of  $\sqrt{N} \sim N^{\frac{3}{4}}$  give us the best results in shock location and strength. It can be proven that in this range of modes (2.14) will not fail in the presence of possible transition points in the numerical solutions. The errors of (3.4)-(3.8)-(3.9) in smooth regions (1.6 away from shock when it appears), at  $t = 0.8$  (before shock),  $t = 1.42$  (when the shock just develops), and  $t = 2.00$  (after shock) are listed in Table 3. The numerical solu-

tions are displayed in Figures 5-6. The error at  $t = 2.00$ , in logarithm scale, is displayed in Figure 7.

We seem to observe higher than algebraic order in smooth regions both before and after the shock develops. This might be the first time super-algebraic accuracy is observed in a shock capturing spectral scheme solving a nonlinear PDE with shocks. The usual  $O(1)$  Gibbs oscillation near the shock is also absent in all of our calculations. We also notice that the TVB limiter (3.11) does not change the numerical results significantly in the smooth region (see Table 4). Actually, we observe the same order of accuracy in the smooth region, comparing Table 4 with Table 3. This indicates that the scheme (3.4)-(3.8)-(3.9) is by itself very stable.

Finally, we run the usual spectral scheme (i.e., with  $v_N$  in (3.8) replaced by  $P_N u$ ) with the TVB limiter (3.11). The errors in smooth regions (1.6 away from shock) are listed in Table 5 (compare with Table 4). Clearly, we only get first order in smooth regions after the shock develops. This indicates that TVB limiting can make a scheme stable but may not preserve the accuracy.

Example 4: 2-D Steady State. We solve a 2-dimensional scalar conservation law

$$\begin{cases} u_t + \left(\frac{u^2}{2}\right)_x + u_y = 0 & (x, y) \in [0, 2\pi] \times [-1, 1] \\ u(x, 0, t) = \sin x \\ u(0, y, t) = u(2\pi, y, t) & y \in [-1, 1], t \geq 0. \end{cases} \quad (4.3)$$

We know that (4.3) has a steady state solution  $u_\infty(x, y)$ .  $u_\infty(x, y)$  actually will be the solution to (4.2) if we replace  $y$  by  $t$  and set  $u(x, 0) = \sin x$  in (4.2).

As mentioned in Section 3, (3.4)-(3.8)-(3.9) can be extended to 2-dimensional cases, we can use either Fourier or Chebyshev method in each of the spatial directions. To solve for the steady state of (4.3), we use Fourier method in x-direction and Chebyshev method in y-direction. The criteria we set for the steady state is that the relative  $L^1$  residue between two consecutive time stage to be less than  $10^{-6}$ , i.e.,

$$\frac{\|u^{n+1} - u^n\|_{L^1}}{\|u^n\|_{L^1}} \leq 10^{-6}. \quad (4.4)$$

Figure 8 displays the profile of the steady state at  $y = 0.38$  and  $y = 1.00$ . The solid line is the exact solution and the plus signs are the numerical one. 32 points in the x-direction and 8 points in the y-direction are used. Figure 8 is the contour plot for the numerical steady state solution.

16. Abstract <p>In this paper, we present a non-oscillatory spectral Fourier method for the solution of hyperbolic partial differential equations. The method is based on adding a nonsmooth function to the trigonometric polynomials which are the usual basis functions for the Fourier method. The high accuracy away from the shock is enhanced by using filters. Numerical results confirm that no oscillations develop in the solution. Also, the accuracy of the spectral solution of the inviscid Burgers equation is shown to be higher than a fixed order.</p>
